## calculate (String, Object [], INodeHelper)

```
public Object calculate (String functionName, Object [] parameters,
INodeHelper helper)
```

This method is what the function is all about - it performs the required calculation and returns the result.

### Parameters

functionName	the name of the function in the library that needs to be calculated
parameters	the values of function parameters as specified in a rule where the function is used. The given array contains Java objects corresponding to different attribute types (String, Integer, DateHolder etc - see a complete list in the <a href="#">Appendix A</a> )
helper	a call-back interface. Should not be used by custom function libraries.

### Returns

The result of the calculation as a Java object of the type corresponding to the attribute types - see [Appendix A](#). If the function value cannot be calculated for whatever reason (for example, the number of parameters or their types are wrong), null should be returned.
